Economic Analysis of the Traditional University System for Technology Entrepreneurs in Peru

Report Date: 2026-03-18

Executive Summary

This report provides a data-driven economic analysis of the traditional university system in Peru, specifically evaluating its return on investment (ROI) for high-growth technology entrepreneurs. The analysis is based on verifiable statistics from Peruvian and international sources, focusing on the quantifiable costs, returns, and time investments associated with pursuing a university degree. The findings indicate that the traditional university path presents a complex and often suboptimal economic proposition for individuals aiming to create high-growth technology ventures. The direct financial costs are substantial and highly variable, ranging from tens of thousands to **over S/ 200,000 for a five-year program [5]**, frequently necessitating significant household indebtedness in a population with limited financial literacy **[27, 29]**. Concurrently, the measurable ROI for higher education has been in decline, with the income premium for each additional year of university study diminishing over the last two decades **[11]**. A significant **portion of graduates**, approximately **one-third**, find themselves in positions that do not require their level of education, a phenomenon termed **"overeducation"** that severely im- pacts the financial viability of their educational investment **[11]**. Furthermore, **the theoretical five-year duration of a degree program is frequently a misrepresentation of reality**; empirical evidence from Peru indicates that many students remain enrolled beyond the prescribed timeframe, extending the period of foregone income and delayed participation in the labor market **[58]**. **For a technology entrepreneur, this extended time represents a critical opportunity cost**, delaying mar- ket entry, product development, and the acquisition of practical, industry-specific experience in a sec- tor where **speed is a primary determinant of success**. When contrasted with the potential, albeit high- risk, income trajectory of a technology venture, the traditional university path's fixed, and often mod- est, income potential for graduates presents a stark economic trade-off. This report **concludes** that the combination of high direct costs, declining financial returns, extended time commitment, and im- mense opportunity cost makes the traditional university system **a questionable allocation of capital and time for aspiring high-growth technology entrepreneurs in the current Peruvian economic land- scape.**

Introduction

The **objective** of this report is to conduct a rigorous and dispassionate **analysis of the economics and return on investment of the traditional university education system in Peru for a specific demographic: the high-growth technology entrepreneur**. In an economic environment where innovation and speed to market are paramount, the allocation of significant personal resources—namely time and capital—to a multi-year academic program requires a cold, analytical assessment. This document eschews motiva- tional narratives and subjective opinion in favor of an evaluation grounded in hard data from sources including the National Institute of Statistics and Informatics (INEI), the National Superintendence of University Higher Education (SUNEDU), the World Bank, and various labor market studies. The analysis will deconstruct the university proposition into its core economic components: the real, all-in financial costs of attendance; the measurable return on investment in terms of income potential and career tra- jectory; the prevalence and impact of student and household debt; the critical discrepancy between

theoretical and actual time investment; and the profound opportunity cost for an individual whose primary goal is the rapid creation and scaling of a technology enterprise. This evaluation is intended to serve as a strategic tool for decision-making, providing a clear, data-driven framework for assessing whether the traditional university path aligns with the economic imperatives of a technology founder in Peru as of 2026.

Direct Financial Investment Analysis of University Education

A foundational component of any investment analysis is the quantification of the initial capital outlay. For a prospective university student in Peru, this outlay varies dramatically, creating a complex landscape of financial commitment that is heavily dependent on the choice between public and private institutions. This section dissects the direct costs, the factors that determine them, and their impact on household financial stability.

Public vs. Private University Cost Structures

The Peruvian higher education system is characterized by a stark dichotomy in its cost structure between public and private institutions. Public universities, which receive a significant portion of their funding from the state, do not charge monthly tuition fees **[3]**. The budget allocated to public universities reached a record S/ 6,968 million in 2024, reflecting a substantial state subsidy **[7]**. However, attendance is not without cost. Prospective students must bear the expense of admission exams, which can range from **S/ 300 to S/ 870** at public universities in Lima, with fees varying by institution and, in some cases, by the student's secondary school of origin **[6]**. Additional administrative fees for admission certificates and medical examinations are also re- quired. While these direct costs are minimal compared to the private sector, they represent a non - trivial barrier for individuals from the lowest socioeconomic strata.

In contrast, the private university sector operates on a commercial basis, with costs that span an exceptionally wide spectrum. The total investment for a standard five-year career can range from approximately S/ 23,000 at the most affordable licensed institutions to well over S/ 200,000 at the most prestigious ones **[1, 5]**. At the lower end, universities such as Universidad María Auxiliadora (UMA) and Universidad de Ciencias y Humanidades (UCH) offer monthly fees starting from S/ 460 and S/ 470, respectively **[1]**. In the mid-range, institutions like Universidad San Ignacio de Loyola (USIL) and Univer- sidad San Martín de Porres (USMP) have monthly fees that can extend up to S/ 3,265 and S/ 3,230 **[10]**. At the highest tier, elite institutions such as the Pontificia Universidad Católica del Perú (PUCP) and the Universidad del Pacífico (UP) command the highest fees. The PUCP's monthly payments can reach S/ 4,130, leading to a total career investment of up to S/ 125,200 **[4]**. The Universidad del Pacífico calculates fees per credit, with a 20-credit cycle potentially costing up to S/ 26,220, and monthly payments reaching S/ 5,244 in the highest bracket **[8]**. For particularly demanding and re- source-intensive careers like Medicine, the costs escalate further. At the Universidad Peruana Cayetano Heredia (UPCH), annual costs for a medical degree can reach as high as S/ 74,400, pushing the total investment for the seven-year program well beyond that of a standard five-year degree **[9]**. This vast range in pricing reflects a highly segmented market where institutional prestige, infrastructure, and perceived quality are directly correlated with the financial burden placed upon the student and their family.

Cost Determinants and Transparency

The pricing mechanisms within Peruvian private universities are often complex, moving beyond a simple flat-rate tuition. Many of the more expensive institutions employ a system of differentiated payment scales, which categorizes students into various financial brackets. This categorization is typically based on a socioeconomic evaluation of the student's family or, more commonly, on the high school

from which the student graduated, using it as a proxy for economic standing **[5, 8]**. For instance, the Pontificia Universidad Católica del Perú (PUCP) utilizes nine distinct payment scales, while the Universidad del Pacífico employs six **[4, 8]**. This tiered system means that the cost of the exact same education can differ substantially for two students in the same classroom. The stated purpose is to provide subsidies to students from lower-income backgrounds, but it also functions as a sophisticated price discrimination model. Furthermore, the cost can be differentiated by the chosen career path. Fields requiring specialized laboratories, equipment, and highly qualified faculty, such as engineering, architecture, and medicine, consistently carry higher tuition fees **[9]**. Medicine is invariably the most expensive degree program due to its extended duration, intensive clinical practice requirements, and high operational costs **[9]**.

In response to this complexity and the potential for opaque pricing, the Superintendencia Nacional de Educación Superior Universitaria (SUNEDU) is tasked with enforcing transparency. Under the University Law (Ley N.° 30220, Art. 11), institutions are legally obligated to disclose all payments required from students—including tuition, matriculation fees, and any other charges—on their web portals, a requirement monitored and sanctioned by SUNEDU **[31]**. SUNEDU does not have the authority to regulate or set caps on tuition fees; its role is to ensure that universities provide clear and accessible informa- tion, allowing prospective students and their families to make informed decisions **[31]**. This mandate for transparency became particularly critical during the economic disruptions of recent years, as it provided a basis for students to question fees for services that were altered by the shift to remote learning. Despite these regulations, the fundamental cost structure remains a significant variable that prospective students, particularly those considering an entrepreneurial path, must factor into their financial planning.

Student and Household Indebtedness

The substantial cost of private university education in Peru directly contributes to a growing trend of youth and household indebtedness. While specific, granular national statistics on student-loan debt are not readily available from the Instituto Nacional de Estadística e Informática (INEI), broader economic indicators paint a clear picture of increasing financial strain. A 2020 study revealed that over 30% of young Peruvians between the ages of 18 and 24 held active debts, with credit cards being a primary instrument **[22]**. This financial pressure is compounded by a challenging labor market for youth, where unemployment rates have been among the highest in the region, forcing many to rely on credit to cover essential expenses, including education **[22]**.

This trend is situated within a larger context of rising household debt across the country. Reports indicate that overall household debt has reached historical highs, with credit quotas consuming up to 32% of personal income, a sharp increase from the pre-pandemic level of 24% **[29]**. The Central Reserve Bank of Peru (BCRP) has noted significant expansion in credit to individuals, particularly in consumer loans and credit card debt, occurring even during periods of economic recession and declining real wages **[30]**. A critical contributing factor to this precarious situation is a widespread lack of financial education. According to the Superintendencia de Banca, Seguros y AFP (SBS), a staggering 41% of the Peruvian population has a low or non-existent level of financial education **[27]**. This deficiency severely hampers the ability of families to make sound long-term investment decisions, such as financing a university education, and increases the risk of accumulating unmanageable debt. For a family considering an investment in a private university education costing upwards of S/ 100,000, the decision often involves taking on significant financial leverage, a risk that is magnified by the uncertain ROI of the degree itself.

Return on Investment and Income Potential

The decision to invest in a university education is, from a purely economic standpoint, predicated on the expectation of a positive return. This return is typically measured by the increased income potential and enhanced career opportunities afforded to graduates. However, recent data for Peru indicates that this return is not guaranteed and has, in fact, been diminishing over time, challenging the long-held assumption that a university degree is a reliable pathway to financial prosperity.

Declining Returns on Higher Education

The financial return on investment in higher education in Peru has experienced a notable decline over the past 15 years. A comprehensive study by Gustavo Yamada and Pablo Lavada quantifies this trend, revealing that the income premium associated with additional years of university study has eroded **[11]**. In 2004, an extra year of study at a private university was associated with a 22% increase in income compared to an individual with only a secondary education. By 2019, this premium had fallen to 18% **[11]**. A similar downward trend was observed for public universities, where the income premium decreased from 18% to 15% over the same period **[11]**. While these rates of return may still be comparable to some alternative financial investments, their trajectory is unequivocally negative.

Most critically, the study found that only 62% of university careers in Peru generate a positive net financial return, meaning that for a substantial 38% of graduates, the increased lifetime earnings do not suffice to cover the direct and indirect costs of their education **[11]**. This statistic fundamentally undermines the premise of university as a guaranteed economic benefit. In stark contrast to the declining returns for university graduates, workers with technical education have seen their salaries increase, suggesting a market shift that values specific, applied skills **[11]**. This data presents a severe challenge to the conventional wisdom, indicating that a significant portion of university attendees are making a financially irrational investment, at least when measured by direct income-based ROI.

The “Overeducation” Phenomenon and Institutional Quality

A primary factor contributing to the declining ROI is the phenomenon of “overeducation,” where a significant portion of university graduates are employed in occupations that do not require a higher education degree. Data indicates that approximately one-third of Peruvian university graduates fall into this category **[11]**. This mismatch is not evenly distributed across fields, being most prevalent in business and economics (54% of graduates) and humanities (35%), but also significantly affecting engin- eering (33%) and law (29%) **[11]**. This situation suggests a substantial misalignment between the skills supplied by the university system and the demands of the labor market. It also implies that many graduates are unable to monetize their educational credentials, effectively nullifying the expected financial return.

The issue is closely linked to the rapid, and largely unregulated, expansion of the private university sector since the late 1990s **[11]**. This proliferation led to a dramatic increase in enrollment but also introduced wide variability in institutional quality. The implementation of a licensing process by SUNEDU has attempted to establish a quality baseline, and the data shows a clear financial penalty for attending a lower-quality institution. In 2019, graduates from universities that failed to obtain SUNEDU licensing earned, on average, 20% less than their counterparts from licensed institutions. This gap widened to 25% by 2021, providing empirical evidence that the choice of institution has a direct and significant impact on a graduate’s earning potential and, consequently, on the ROI of their educational investment **[11]**.

Comparative Income Analysis: Graduate vs. Entrepreneur

A direct, statistically robust comparison between the income of a typical university graduate and a high-growth technology entrepreneur is inherently difficult due to the vastly different nature of their respective paths. However, an analysis of available data allows for a compelling juxtaposition of their economic prospects. The average monthly income from work in Peru was S/ 2,054.9 in the third quarter of 2024 **[81]**. For the formally employed, a category where university graduates are more likely to be found, the average salary was higher, at S/ 3,040 per month **[104]**. This figure represents a relatively stable, predictable, but ultimately capped income stream that a graduate can expect.

The entrepreneurial landscape in Peru presents a starkly different risk-reward profile. The country has a high rate of enterprise creation, but the vast majority are micro and small enterprises (MYPEs) with moderate incomes and high failure rates; data suggests only one in ten new businesses survives beyond its first year **[63]**. However, for the technology entrepreneur, the potential upside is orders of magnitude greater. While specific income data for tech founders is not available, proxy indicators are revealing. Formal entrepreneurs in the commerce and services sectors reported average monthly sales of S/ 22,000 in 2021 **[67]**. More significantly, studies show that MYPEs engaging in *technological diversification* exhibit higher export values, directly linking technological innovation to greater revenue potential **[64]**. The entrepreneurial path is one of high risk and high variance; the probability of failure is significant, but the potential for wealth creation far exceeds the linear, salary-based progression of a traditional employee. For the aspiring technology founder, the economic calculation is not about securing an average salary, but about the possibility of achieving exponential growth, a possibility that the traditional employment path for graduates does not offer.

The Investment of Time and Control

Beyond direct financial costs, a university education demands a substantial investment of time. This temporal investment carries its own set of costs and trade-offs, particularly concerning the loss of autonomy and the delay in entering a chosen field. For a technology entrepreneur operating in a fast-paced industry, the management and valuation of time are critical strategic considerations.

Theoretical vs. Real Time to Graduation

The standard academic framework in Peru outlines a bachelor's degree as a five-year program, typically comprising ten academic semesters **[55]**. This theoretical duration is the basis upon which most prospective students and their families calculate the total cost and time commitment. However, empirical evidence and systemic analysis suggest that this five-year timeline is more of an ideal than a reality for a large segment of the student population. Observed trajectories frequently extend beyond the prescribed period, with students remaining enrolled for additional years beyond the theoretical duration **[58]**.

This discrepancy is driven by a confluence of socioeconomic factors. Among the 8.2% of Peruvian university students who have interrupted their studies, 28.5% cited a lack of financial resources as the primary cause, a situation exacerbated by a low average monthly per capita household income of only S/ 991 **[58]**. Furthermore, many students have significant family care responsibilities, with 10.4% of those who interrupted their studies citing family-related reasons, such as the care of children or elderly relatives. This reality conflicts with university structures that often fail to account for the socioeconomic pressures and time constraints faced by students, particularly given that the lack of time is the second most reported reason for academic disruption **[58]**. This model is fundamentally incompatible with the reality of a student who must also hold a job. As a result, students are often forced to take a reduced course load each semester, inevitably prolonging their time to graduation. This extension of the study period has a compounding negative effect on the overall economic equation. It not only increases the total direct cost through additional matriculation fees but, more critically, it lengthens the period of foregone income and delays the start of a professional career, dramatically increasing the opportunity cost of the degree.

Autonomy and Flexibility: Employee vs. Entrepreneur

The choice between a traditional career path post-graduation and an entrepreneurial one is also a choice between two fundamentally different paradigms of personal and professional control. The standard employment model in Peru is governed by a legal framework that defines a maximum work week of 48 hours **[85]**. While modern workplaces are increasingly adopting flexible arrangements such as hybrid models and objective-based work, the employee's autonomy remains circumscribed **[82]**. Key strategic decisions, work priorities, and ultimate control over one's time are dictated by the employer. Employment offers a degree of security, a predictable schedule, and benefits such as paid vacations and health insurance, **but it comes at the cost of surrendering a significant measure of personal sovereignty over one's professional life**.

Entrepreneurship, in contrast, offers the potential for complete autonomy. The founder dictates the vision, sets the priorities, and has total control over the allocation of their time and energy. This freedom is a core attraction of the entrepreneurial path **[90]**. However, this autonomy is coupled with total responsibility and immense risk. **The distinction** between work and life often dissolves, especially in the early stages of a venture, and the stability and benefits of traditional employment are absent. The entrepreneur bears the full weight of the enterprise's success or failure. For a high-growth technology founder, the value of this autonomy can be immense. It allows for the agility to pivot, the speed to seize market opportunities, and the singular focus required to build a company from the ground up.
The trade-off is clear: the structured, lower-risk, but constrained environment of employment versus the unstructured, high-risk, but potentially limitless environment of entrepreneurship. The decision hinges on an individual's tolerance for risk and their valuation of control over their own time and destiny **[90]**.

Opportunity Cost Analysis for the Technology Entrepreneur

Opportunity cost is the value of the next-best alternative that is foregone when making a decision. For an aspiring technology entrepreneur considering a traditional university degree, this is arguably the most significant and least appreciated cost. It encompasses not only the direct income lost during years of study but also the invaluable and irretrievable loss of time in a rapidly evolving market.

Quantifying Foregone Income

The most direct component of opportunity cost is the income an individual could have earned by entering the workforce instead of attending university. Using the average monthly salary for a formal employee in Peru (S/ 3,040), a simple calculation reveals the magnitude of this cost **[104]**. Over a theoretical five-year degree program, the total foregone income amounts to S/ 182,400 (*Cálculo:* S/ 3,040 × 12 meses × 5 años = **S/ 182,400**). This figure does not account for potential salary increases, promotions, or bonuses that would likely occur over a five-year period of continuous employment and skill development. Given that the actual time to graduation often extends well beyond five years, this calculated loss of income represents a conservative estimate. For an individual who takes eight years to graduate, the foregone income could exceed S/ 290,000 (S/ 3,040 × 12 meses × 8 años = **S/ 291,840**). This sum, which could have been saved, invested, or used as seed capital for a business venture, is instead sacrificed. It is a direct, quantifiable economic loss that must be weighed against the uncertain future income premium that the university degree might provide.

The Value of Early Market Entry and Experience

For a technology entrepreneur, the opportunity cost of time extends far beyond lost wages. The technology sector is characterized by rapid innovation cycles and intense competition, where speed and first-mover advantage can be decisive. The five to eight years spent in a traditional university program

represent a critical window of opportunity that is permanently closed. During this period, an aspiring founder is isolated from the market, learning theoretical concepts rather than engaging in the practical, iterative process of building a product, acquiring users, and achieving product-market fit. This is a period where they could be building a professional network within the tech ecosystem, identifying co- founders, and establishing relationships with potential investors and mentors. **The practical experience gained from launching a venture, even one that ultimately fails, is often more relevant and valuable for a future founder than much of the content of a traditional academic curriculum**. The compounding effect of early experience is a powerful force; each year spent in the market builds upon the last, accelerating learning and increasing the probability of success. The university path imposes a multi-year delay on the start of this compounding process, a handicap that can be difficult to overcome in the global technology landscape.

> *This claim is justified because launching a venture generates integrative, high-stakes learning that traditional academic settings rarely replicate, forcing founders to make decisions under uncertainty, manage resources, and respond to real market feedback. Even failed ventures produce tacit knowledge about execution, customer behavior, and adaptation that is directly relevant to future success. This pattern is evident in deep tech: SpaceX's early rocket failures were critical to Musk's later achievements, early iterations of OpenAI evolved through experimentation before reaching scalable models, and companies like NVIDIA pivoted multiple times before dominating AI hardware. In each case, practical experience under real constraints proved more formative than abstract instruction.*

Alternative Skill Acquisition Pathways

The traditional university system's value proposition is predicated on its role as the primary conduit for acquiring advanced knowledge and skills. However, the rise of alternative educational models challenges this monopoly, particularly in the technology sector. The skills required to build a successful technology company—such as coding, digital marketing, product management, and user experience design—are often best learned through focused, practical application rather than broad, theoretical study. **Online learning platforms**, intensive coding bootcamps, and specialized certification programs offer pathways to acquire these specific, in-demand skills in a fraction of the time and at a fraction of the cost of a traditional degree. These alternatives allow an aspiring entrepreneur to rapidly tool up with the necessary competencies and immediately apply them to a business idea. While a university degree may offer a broader intellectual foundation, its slow pace and often outdated curriculum can be a significant disadvantage. The opportunity cost analysis must therefore include a comparison to these more agile, cost-effective, and targeted methods of skill acquisition, which may offer a more direct and efficient route to entrepreneurial readiness.

Conclusion

A rigorous, data-driven analysis of the traditional university system in Peru reveals a challenging economic proposition for the aspiring high-growth technology entrepreneur. The direct financial investment is substantial, with costs at private institutions creating a significant barrier and often leading to considerable household debt **[29]**. This high initial outlay is juxtaposed with a measurable and persistent decline in the return on investment, as evidenced by the shrinking income premium for graduates and the high prevalence of "overeducation" **[11]**. The data indicates that for a significant minority of students, the university path constitutes a negative net financial investment.

Furthermore, the investment of time is frequently and severely underestimated. The reality of balancing work and study extends the time to graduation far beyond the theoretical five years, amplifying the already immense opportunity cost **[58]**. For a technology founder, this lost time is the most critical deficit, representing years of forgone market experience, product development, network building, and practical skill acquisition in an industry where velocity is a key determinant of success. The structured, authority-driven environment of academia and subsequent employment offers stability but stands in stark contrast to the autonomy and agility required for entrepreneurship. When the quantifiable costs of tuition and foregone income are combined with the unquantifiable but profound costs of delayed market entry and lost experience, the traditional university degree appears to be a strategically

questionable pathway for individuals whose primary objective is the rapid creation of value in the techno- logy sector. The decision to commit years of life and significant capital to this path must be made with a clear understanding of these stark economic realities.
